## Editorial

As you are aware, in the last issue of a year next to the quarterly reporting we also present a summary of rabies cases and the total number of animals tested for rabies in Europe for the previous year. With 9,830 cases (including 9 human rabies cases and 35 bat rabies cases) in 2005 the total number of rabies cases has increased by 80% compared to 2004 reaching approximately a similar level as in 2003. Interestingly, this increase is based on a 2 to 2.3 fold higher reporting of rabies cases from Russia and Ukraine, respectively. A similar tendency applied for Turkey, where dog mediated rabies is the main problem. Whether this increase is a result of improved surveillance or a result of a deterioration of the rabies situation in those countries remains unclear yet.

In the miscellaneous article we refer to recommendations of the 1<sup>st</sup> international conference "Rabies in Europe" held in Kiev, Ukraine, 15-18 June 2005 by providing protocols for the passive and active surveillance of bat rabies as developed by a MED-VET-NET working group (see also RBE 2/2005). We would also like to draw your attention to a recent important WHO publication on rabies. The First Report of the WHO Expert Consultation held in Geneva from 4 – 8 October 2004 (WHO Technical Report Series, No 931) is now available.

And finally on a personal note: Our principal editor Carsten Pöttsch will change his position within the institute and will no longer be available. During the next three years he will work for a FAO project on food-and mouth disease in Caucasian countries. We very much appreciate his work as an editor of the Rabies Bulletin Europe. He introduced changes in the way the rabies data are presented nowadays to make the interpretation of the European data clearer. The collaborators and colleagues of the WHO Collaborating Centre for Rabies Surveillance and Research wish him all the best for the future.

To guarantee a continuous publishing of the Rabies Bulletin Europe Carsten Pöttsch will be replaced by Conrad Freuling as our new principal editor.

Thomas Müller, Conrad Freuling

### 3.1 PASSIVE AND ACTIVE SURVEILLANCE OF BAT LYSSAVIRUS INFECTIONS

Med-Vet-Net working group

A national bat rabies surveillance network should be established in all European countries in close collaboration with bat specialists including international bat agencies. Bats are protected species; hence sampling for surveillance for bat lyssavirus infections has to comply either with regulations of Council Directive 92/43/EEC of the European Union on the conservation of natural habitats and of wild fauna and flora, with the Agreement on the Conservation of Bats in Europe, EUROBATS, 1991 or national legislation. Three potential bat lyssaviruses can occur in Europe; EBLV-1 & -2 in Western and Central Europe and Westcaucasian bat virus in eastern parts of Europe, respectively. The following protocols for passive and active surveillance are based on recommendations of the First International Conference "Rabies in Europe", Kiev, Ukraine, 2005.

#### **PROTOCOL FOR PASSIVE SURVEILLANCE**

Passive surveillance is based on the testing of sick, rabies suspect (showing clinical signs or abnormal behaviour) or dead bats of all indigenous bat species for lyssavirus infections. Also, bats involved in contact incidents, e.g. biting or scratching, or animals caught by pets should be included. Further sources of frozen or formalin preserved bat samples can be archives of zoological institutions or private bat collections. All dead bats (regardless of species) should be submitted to the National Rabies Reference Laboratory for lyssavirus testing.

Brain sample collection using a needle through the orbit of the eye socket can be used to cause minimal disruption to the bat skull and allow species

identification. The bat can then be archived as a specimen. Identification of sample bats into species should be performed by bat specialists only or by specialized laboratories using DNA analysis of patagium tissue samples. This method can be important for distinguishing closely related bats such as sibling species.

The method of choice for lyssavirus antigen detection on brain smears is the Fluorescent Antibody Test (FAT) in accordance with WHO guidelines. FAT positive brain samples should be stored for further analysis. For virus characterisation of all lyssavirus positive bats standard sequencing techniques as described should be applied. It is intended to collate and archive sequence data across Europe on a common database. For laboratories that do not have capacity to carry out sequencing, assistance may be provided by other European laboratories. Collection of salivary glands or neck tissue of rabies positive bats can also be useful.

#### **PROTOCOL FOR ACTIVE SURVEILLANCE OF BAT RABIES**

Active surveillance is based on the monitoring of free-living indigenous bat populations for lyssavirus infections. The focus of research can either be on the screening of all abundant bat species or on the surveillance of high risk bat species in a particular area. Sampling has to be done without damaging bat populations: killing bats for active surveillance is illegal and unacceptable.

Capturing of bats should be conducted in close collaboration with bat conservationists. Bats can best be captured when leaving their shelters using mist-nets, harp traps, hand-nets, etc., according to the particular roosting

sites. Sampling should be performed on an annual basis, preferably in the same month in order to get comparable data. Avoid repeated sampling in the same year because it could cause excessive disturbance to bat colonies.

Blood sampling of bats requires skills, expertise and training to avoid serious injuries. The most efficient and harmless procedure is lancing veins, e.g. interfemoral vein (uropatagium) as well as antebrachial vein (propatagium). Veins in the patagium membranes should not be used because of the risk of damages. Strictly avoid cardiac puncturing. Blood should quickly be aspirated through a syringe or pipette and transferred to an eppendorf vial and stored appropriately prior to testing. Saliva can be collected using cotton swabs and subsequently be stored in either 1 ml of RNA buffer or viral transport medium for RT-PCR testing and virus isolation, respectively. The latter case is recommended since it offers both diagnostic procedures.

Virus neutralising antibodies can be detected using EBLV-modified versions of the Rapid Fluorescent Focus Inhibition Test (RFFIT) taking the small volume and haemolysis of the serum samples

into account. If possible, sera should be tested separately against both EBLV-1 and EBLV-2. Nested RT-PCR or real time PCR as described is recommended for detection of EBLV-specific RNA in saliva swabs. The RNA extraction method may differ depending on the transport buffer. RT-PCR is considered as a highly sensitive screening method whereas virus isolation confirms shedding of viable and infectious virus.

### **DATA COLLECTION**

For both passive and active surveillance the following data should be collected: (i) ring identification number, (ii) species, (iii) gender and reproductive state, (iv) age (estimated by the degree of ossification in fingers' metacarpals and phalanges, together with tooth wear levels), (v) weight (active surveillance), (vi) collector (name, address, tel.no, email), (vii) accurate location, (viii) details of exposure (contact, biting, scratching, part of the body), (ix) information on abnormal behaviour, etc. and (x) diagnostic test results (FAT, PCR, serology and others if applicable). It is recommended to use a uniform sample submission form for data collection.

## **3.2 WHO EXPERT CONSULTATION ON RABIES—FIRST REPORT**

This report of the WHO Expert Consultation on Rabies held in Geneva 4-8 October 2004 covers essential information for rabies prevention and control throughout the world. As more than 99% of all human rabies deaths occur in the developing world, a re-assessment on the true public health impact and the economic burden of the disease is presented in order to strengthen the commitment to rabies control. It also assists public health authorities in better assessing the risk of human rabies as the emergence of new lyssaviruses and changes in rabies epidemiology are being considered. Furthermore, this report reviews recent progress in rabies research, such as classification of rabies viruses, rabies pathogenesis and diagnosis, rabies pre- and post-exposure prophylaxis, the

management of rabies patients, and canine as well as wildlife rabies prevention and control.

The report also outlines the priorities for basic research, as well as those for operational research for sustainable canine rabies control, including dog population management schemes complying with animal welfare principles. Such operational research is necessary for removing or alleviating the main constraints to rabies control in dogs, as these are the source of most human rabies cases worldwide.
